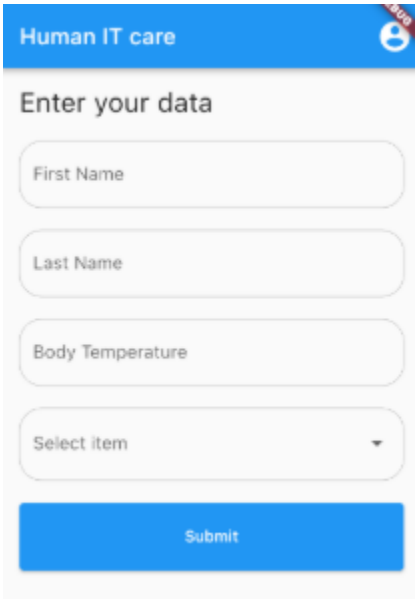
Aim: To create an interactive Form using form widget

Theory:

The Form widget in Flutter is used to group multiple form fields and manage their validation and state. It acts as a container for form elements like TextFormField, Checkbox, Radio, and others, and provides functionality to validate, reset, and save the form's data. By using a GlobalKey<FormState>, you can access the form's state, trigger validation, and update the form's fields. This allows for interactive forms where user inputs can be validated before submission

Output:



Conclusion:

Hence we successfully created interactive form using flutter.
